# CS 1541 Introduction

## Technology Constraints

Wonsun Ahn

Department of Computer Science

School of Computing and Information

# Technology Constraints

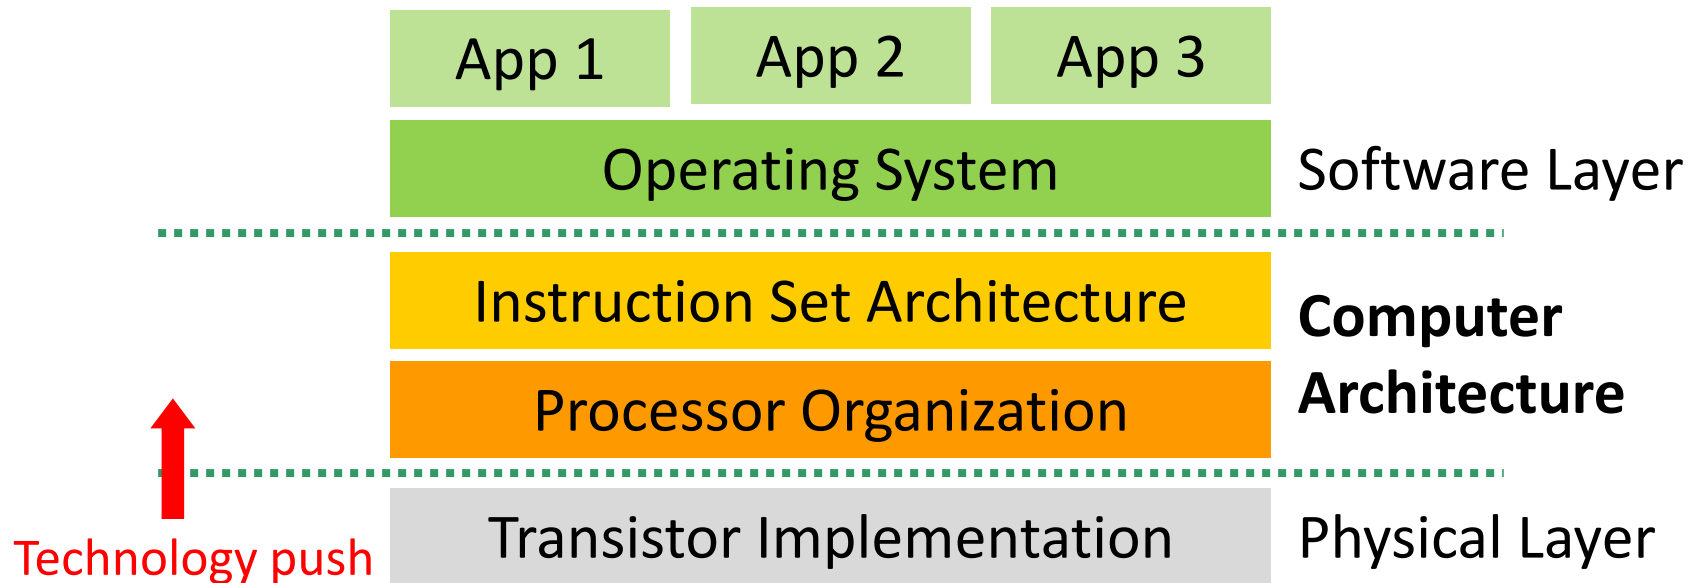

---

# Technology Constraints

- Constraints in technology push architecture too

- *Power Wall*: Thermal Design Power (TDP) constraint
- *Memory Wall*: Constraint in bandwidth to memory
- *Variability*: Limits in the precision of manufacturing technology

- Processor must be designed to meet all constraints

# Power Wall

- $\text{Power}_{\text{CPU}} = \text{Power}_{\text{dynamic}} + \text{Power}_{\text{leakage}}$   
 $\text{Power}_{\text{dynamic}} \propto A * N * CFV^2$   
 $\text{Power}_{\text{leakage}} \propto f(N, V, V_{\text{th}}) \propto N * V * e^{-V_{\text{th}}}$ 
  - Leakage power is also called *static power*
  - This total CPU power cannot exceed TDP
  
- Moore's Law transistor scaling means two things:
  - $N$  = Number of transistors ↑ ↑
  - $C$  = Capacitance ( $\propto$  transistor size) ↓
  - Reductions in  $C$  does not compensate for increases in  $N$
  
- Architects must use tricks to keep power in check
  - To keep packing more transistors to increase performance

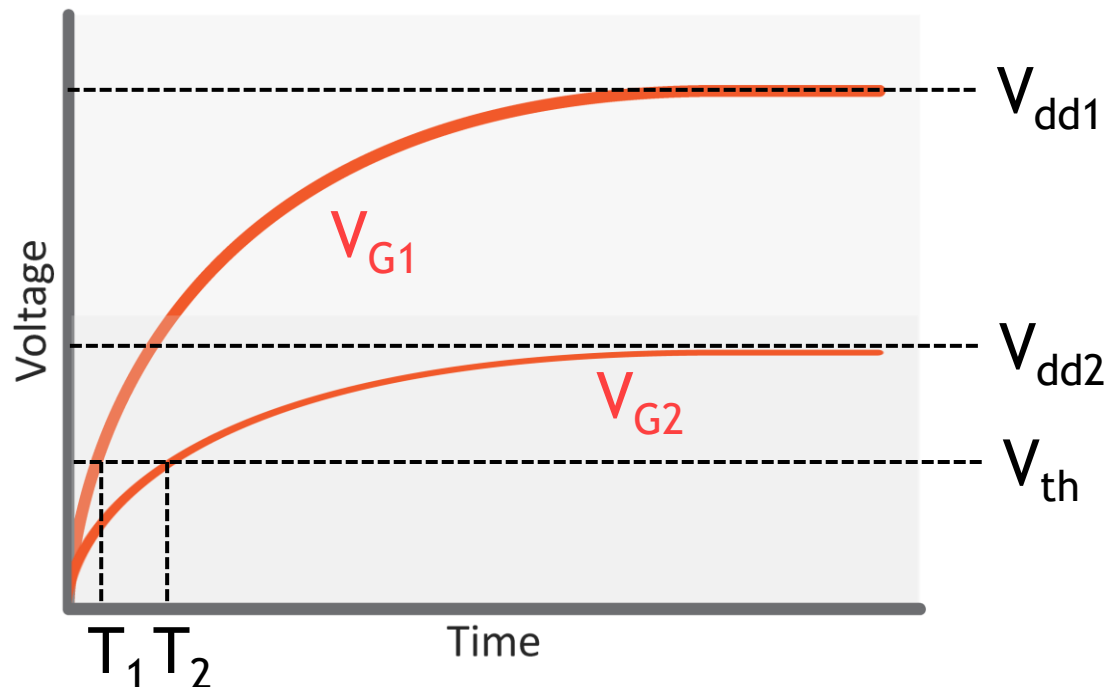

# 1. Reducing Dynamic Power

- $\text{Power}_{\text{dynamic}} (\propto A * N * CFV^2) + \text{Power}_{\text{leakage}} (\propto N * V * e^{-V_{th}})$
- Reducing A (Activity): *Clock gating*
  - Disables the clock signal to unused parts of the chip (idle cores)
  - Wake-up is instantaneous (the moment clock signal goes in)
- Reducing F (Frequency) and V (Supply Voltage)
  - When F is reduced, V can also be reduced (Transistor 101 and water pressure, remember?)
  - *Dynamic Voltage Frequency Scaling (DVFS)* done on multi-cores
    - Slow down low-priority cores, speed up high-priority cores

# DVFS and Clock Speed

## ■ RC Charging Curve of $V_G$

- $V_{dd1} \rightarrow V_{dd2}$  saves power, but slows down  $T_1 \rightarrow T_2$
- $V_{dd2} \rightarrow V_{dd1}$  uses more power, but speeds up  $T_2 \rightarrow T_1$
- $V_{dd} \propto 1/T \propto F$  ( $V_{dd}$  is proportional to frequency)

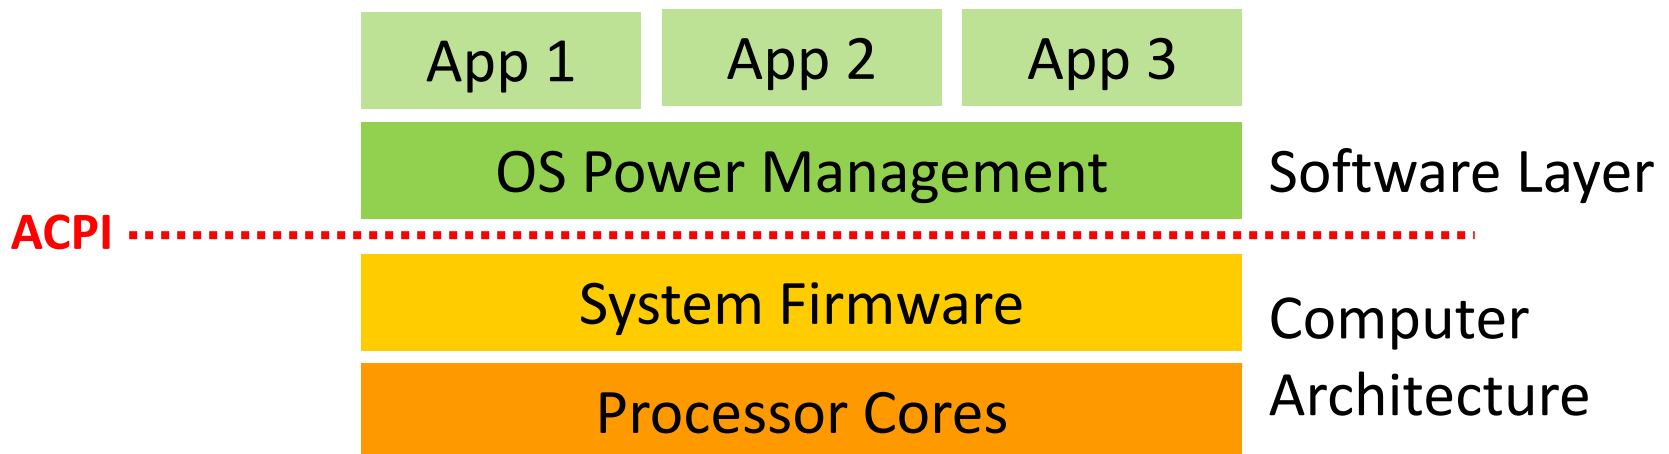

## 2. Reducing Leakage Power

- $\text{Power}_{\text{dynamic}} (\propto A * N * CFV^2) + \text{Power}_{\text{leakage}} (\propto N * V * e^{-V_{th}})$
- Reducing N (Transistor Number): *Power gating*
  - Disables power to unused parts of the chip (unused cores)
  - Eliminates dynamic power *and* leakage power to those parts
  - Drawback: wake-up takes a much longer time than clock gating
    - Delay for supply voltage to stabilize
    - Delay to backup and restore CPU state to/from memory
- Reducing V (Supply Voltage): *DVFS* also helps here
- Increasing  $V_{th}$  (Threshold Voltage)
  - For transistors that are not critical to maintaining CPU frequency

# OS Manages Power

- Who decides which cores to clock gate and power gate?
- Who decides how to apply DVFS to the cores?
- *ACPI (Advanced Configuration and Power Interface)*
  - OS performs power management using this interface
    - OS knows best which threads to prioritize for best user experience
  - Open standard interface to system firmware
    - Firmware sends signals to processor cores to control them

# 3. Simpler Processor Design

- Plenty of transistors but not enough power
  - Power becomes the ultimate currency in processor design
- To eke out the last bit of performance out of a thread
  - Architects must use increasingly complex logic (more power)
  - Diminishing returns on performance for power investment
- Push towards simpler architectures:
  - *Multi-cores*: Run multiple programs (threads) on simple cores
  - *GPUs*: Run each instruction on massively parallel compute units
  - *Caches*: Memory caches are power efficient (low dynamic power)

# Memory Wall

- Refers to both *latency (ns)* and *bandwidth (GB/s)*
  - CPU frequency and overall performance increased dramatically
  - Memory (DRAM) latency and bandwidth have lagged far behind
- Why?
  - Limit on the number of CPU / DRAM pins that can be soldered on

- DRAM manufacturers have traditionally prioritized capacity
- DDR1 (1998): 1.6 GB/s → DDR4 (2014): 25.6 GB/s  
(Impressive? Not so much compared to CPU performance)

# Memory Wall

Source: SC16 Invited Talk “Memory Bandwidth and System Balance in HPC Systems” by John D. McCalpin

■ FLOPS = floating point operations per second (performance)

# Memory Wall

- Where did the Memory Wall push architecture?
- *Caches*: If hit in cache, no need to go to memory
  - Caching reduces both data access latency/bandwidth
- *3D-Stacked Memory*: Stack CPU on top of memory
  - Drill vias, or holes, through silicon to bond CPU with memory
  - Through silicon vias (TSVs) have low latency / high bandwidth

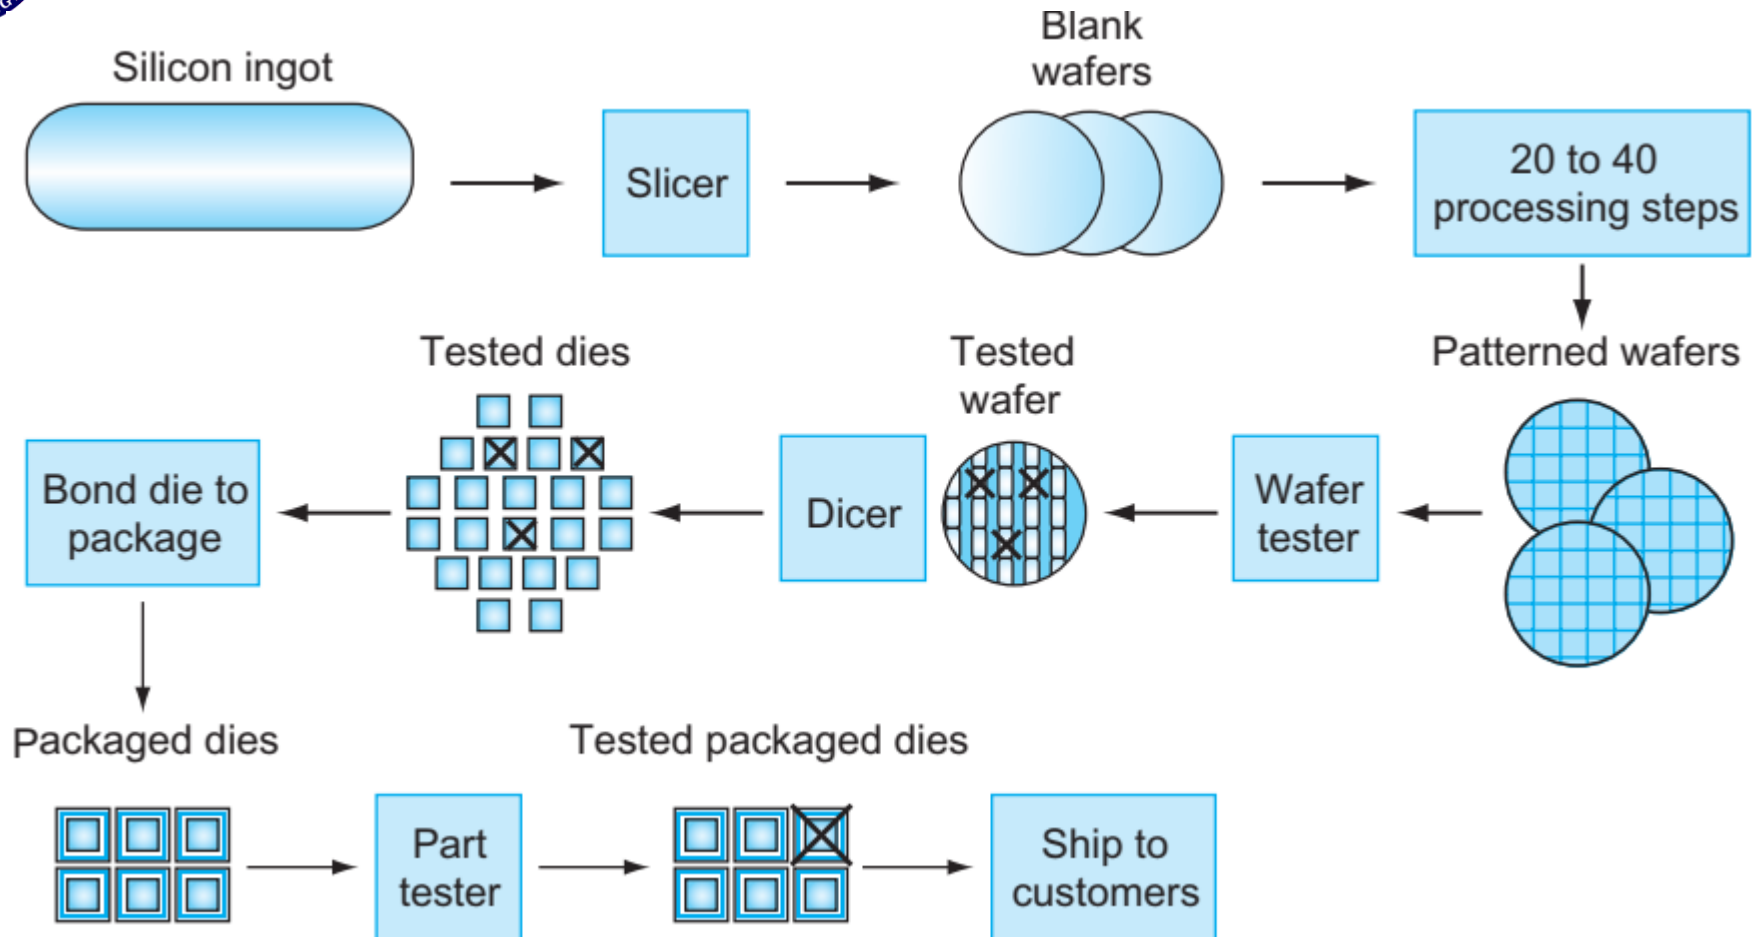

# Variability

- *Variability*: differences in speed of individual transistors
  - Nowadays, transistor dimensions measure just dozens of atoms!
  - If fab can't ensure uniformity of transistors, speeds will differ
  - Speed differences mostly come from variations in  $V_{th}$ :
    - low  $V_{th}$  → cycle time ↓ but power ↑
    - high  $V_{th}$  → cycle time ↑ but power ↓
- If unlucky and a logic path has lots of slow transistors
  - CPU may miss clock cycle time if path is exercised
  - CPU must be discarded, since it malfunctions
  - Leads to low chip *yield*

# Wafer Yield

- Yield is 85% (17 out of 20 tested dies or chips)
- Lower yield leads to higher production cost

# Variability

- Where did Variability push architecture?
- *Product binning*: Sell slower CPUs at a cheaper “bin”
  - And rate slower CPUs at a lower CPU frequency
  - Instead of discarding them as “malfunctioning”
- *Multi-cores*: Easy to disable one or two buggy cores
  - Compared to single core where subcomponents must be disabled
  - Used when one or two cores are extremely slow
- *Limited pipelining*: pipelining exacerbates variability
  - With long stages, many transistors so tend to even each other out
  - With short stages, few transistors so probable all are slow

# Intel i9 Product Binning

Model	# Cores	# Threads	Base Clock	All Core Turbo	Turbo Boost	Total L3 Cache	PL1 TDP
i9-10900K	10	20	3.7	4.8	5.1	20	125
i9-10900KF	10	20	3.7	4.8	5.1	20	125
i9-10900	10	20	2.8	4.5	5.0	20	65

i5-10600K	6	12	4.1	4.5	4.8	12	125
i5-10600KF	6	12	4.1	4.5	4.8	12	125
i5-10600	6	12	3.3	4.4	4.8	12	65
i5-10600T	6	12	2.4	3.7	4.0	12	35
i5-10500	6	12	3.1	4.2	4.5	12	65
i5-10500T	6	12	2.3	3.5	3.8	12	35
i5-10400	6	12	2.9	4.0	4.3	12	65
i5-10400F	6	12	2.9	4.0	4.3	12	65
i5-10400T	6	12	2.0	3.2	3.6	12	35

Why the close to 4X difference?  
Clock difference is just 2X!

Produced from one wafer

\* TDP is calculated using the Base Clock frequency at a nominal supply voltage

# Opportunities for Speed Improvement

- So Dennard Scaling is dead
  - Free CPU frequency gains are no longer there
  
- And we are walled in by technology constraints
  - Power wall
  - Memory wall
  - Variability
  - ...
  
- Where do architects go look for performance?

# Improving Execution Time

- Execution time =  $\frac{\text{instructions}}{\text{program}} \times \frac{\text{cycles}}{\text{instructions}} \times \frac{\text{seconds}}{\text{cycle}}$
- Improving  $\frac{\text{seconds}}{\text{cycle}}$  :
  - *Pipelining* can lead to higher frequencies  
(by having short stages separated by latches)
- Improving  $\frac{\text{cycles}}{\text{instructions}}$  :
  - *Superscalars* can execute multiple instructions per cycle
  - *Multi-cores* execute multi-instructions from multi-threads
- Improving  $\frac{\text{instructions}}{\text{program}}$  :
  - *GPUs* are *SIMD* (*Single Instruction Multiple Data*) processors

# What about Other Performance Goals?

- We talked a lot about execution speed
- But there are other performance goals such as:
  - Energy efficiency
  - Reliability
  - Security
  - ...
- In this class, we will mainly focus on speed
  - Not that other goals are not important
  - We will touch upon other goals when relevant
  - Performance will be used synonymously with speed
